

## Lecture 1

# Database Design and Data Modelling - an Overview

Week 1

This series of lectures introduces:

- Enhanced Entity Relationship (EER) Data Model
- Methods to describe a universe of discourse (a business area) using the EER Data Model
- The Relational Data Model
- Mapping of an EER design onto a Relational Database Implementation
- How to describe and manipulate a relational database using the Structured Query Language (SQL).
- Principles of good database design

2

## Questions you should be able to answer after you studied this module

- How can information (e.g. about an enterprise) be represented ?
- What languages can be used for this task?
- How to manipulate this information (store and retrieve it) ?
- What standards exist?

© 2010 Griffith University

3

## Possible answers

- Use the (Enhanced) Entity Relationship Model to represent data (or IDEF1x, UML, EXPRESS,...)
- Use the Relational Data Model to represent data (or OO, XML,...)
- Use SQL (Structured Query Language) for describing and manipulating data (or OSQL,...)

© 2010 Griffith University

4

## The Universe of Discourse (UoD)

- The UoD is that domain of the enterprise about which information is to be stored in the database (accounting, personnel, materials management, scheduling, product catalog, customers...etc)

5

## Information or Data?

- Data: facts
- Information: interpreted data (what element of news is carried by the data)
- Databases store data but users *interpret* the retrieved data and it becomes information (for them)

6

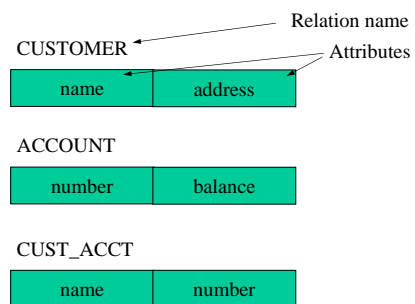

## Example Entity Relationship Diagram

© 2010 Griffith University

7

## Relation schema

© 2010 Griffith University

8

## Relation instance

CUSTOMER

name	address
J smith	22 high st
M hari	77 danger st
G grant	33 low st

Arrows point from the label 'tuples' to the three data rows of the table. Arrows point from the label 'Attribute values' to the 'name' and 'address' headers.

9

## Databases can be queried using

- Relational calculus
- Relational algebra
- SQL

© 2010 Griffith University

10

## Relational calculus

The query

*“Show names and addresses of customers with balances > \$10,000”*

can be expressed as:

$$\{ u, v \mid \text{customer}(u,v) \wedge \text{account}(x,w) \wedge \text{cust\_acct}(u,x) \wedge w > 10000 \}$$

Arrows point from 'Tuple variables' to 'u, v' and from 'Conditions' to the rest of the formula.

11

## Relational algebra

The query

*“Show names and addresses of customers with balances > \$10,000”*

can be expressed as:

$$\Pi_{\text{name,address}} (\sigma_{\text{balance} > 10000} (\text{customer} * \text{account} * \text{cust\_acct}))$$

© 2010 Griffith University

12

## SQL

The query

*“Show names and addresses of customers  
with balances > \$10,000”*

can be expressed as:

SELECT name, address

FROM customer c , account a, cust\_acct ca

WHERE

c.name = ca.name AND

ca.number = a.number AND

a.balance > 10000;

The End
