Lecture 2

What is a Database and a Database Management System?

Week 1

Overview

- Application areas of Databases
- Why use Databases?
- Properties of Database systems
- Structure of a typical Database Management System
- Database People

Application areas of Databases

 Manufacturing, engineering, banking, education, government, health services, tax office, personnel, tourism and travel, information services (libraries, reference material), geographic information systems

2010 Griffith Universit

Why use Databases?

Properties of traditional office information systems:

- bulky
- slow access to the data
- organised for one purpose and hard to use data in them for any other purpose,
- prone to inconsistencies, inflexible (hard to change the way data were stored)

© 2010 Griffith Universit

Why use Databases? (cont'd)

Properties of computer file system

- collection of files in various formats
- for each application using the data, a separate storage format was designed
- each <u>new business need</u> saw <u>new data file formats</u> causing redundancy (and inconsistency)

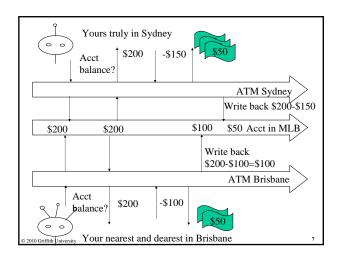

2010 Griffith University

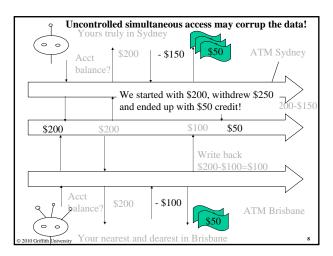

Undesired Effects

- Data redundancy and inconsistency
- *Inaccessibility* (hard to access data to answer arbitrary queries)
- Data isolation (difficult to write new applications)
- Unreliability (simultaneous access may corrupt data)
- No data security (no or insufficient control of who can access which data)
- *Inflexibility* (hard to change storage structure without changing application program)

Definitions

- A Database (DB):
 - is a logically *coherent* collection of data
 - uniformly represents data using a given data model
- A <u>Database Management System (DBMS):</u>
 - is a controlled collection of programs (software)
 - uses a given data model to define, store, retrieve, modify the data stored in it

2010 Griffith Universi

Example DBMSes

- IMS (IBM, hierarchical data model)
- IDMS2 (IBM, network [Codasyl] data model)
- **System R** (IBM, *relational* data model, research prototype, 1970s)
- DB2 (IBM, relational data model)
- Ingres, Tandem, Oracle, Access (independent software vendors, *relational* data model)
- Ontos, O2 (independent software vendors, *object-oriented* data model)

2010 Griffith Univer

Some characteristics...

- Millions of lines of code
- Amount of data managed: gigabytes (~10⁹) to terabytes (~10¹²)
- · Enormous overhead
- Cost: mainframe ~\$100,000 per year

2010 Griffith Universit

Properties of Database systems

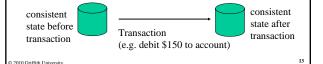

- Control of redundancy
- Uniform access to data (using standard data model)
- Use of query languages
- Efficient data access (optimization)
- Reliable concurrent access
- Integrity maintenance
- Multiple views of data available

2010 Griffith Universit

2

ACID properties...

- Atomicity: any change on the data is either performed or not performed
- <u>Consistency</u>: the database always changes from consistent state to consistent state as a result of a <u>database transaction</u>

ACID properties... (cont'd)

- <u>Isolation</u>: a transaction does not see the intermediary state of database caused by another transaction. If two transactions want to use the same data item, they are *queued up* (or they are scheduled in a way that the effect is *as if* they had been queued up) or *serialized*
- <u>Durability</u>: if a transaction has been performed and committed then the result remains there 'indefinitely'

© 2010 Griffith Universit

Concepts

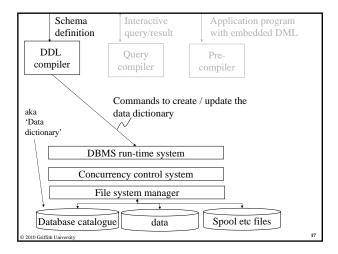

- <u>DDL</u>: data definition language (used to describe the *database schema* (i.e. the structure of the data in the database)
- <u>DML</u>: data manipulation language used to insert, retrieve and update *data* in the database
- <u>Database Catalogue</u>: the part of the database which stores the database schema description

16

Database People

- <u>Database administrator</u> (a well paid job!)
 - [consults users about their needs,]
 - [select what information will be stored]
 - [chooses logical / physical data structures for best performance]
 - [chooses integrity constraints to maintain automatically]
 - monitors performance
 - changes data structures as needed
 - arranges backup and recovery
 - determines access rights

2010 Griffith University

• <u>Database Designer</u> (in large organisations a separate function):

- consults users about their needs,
- select what information will be stored
- chooses logical / physical data structures for best performance
- chooses integrity constraints to maintain automatically

2010 Griffith Universit

- <u>Programmers ('Software engineers')</u>:
 - implement/ test / debug application programs
 - configure software systems
- End users:
 - casual users (occasionally use the DB)
 - naïve (parametric) users (no database knowledge, use DB through application programs only)
 - sophisticated users (directly use database)
 - stand-alone users: personal databases
